

SAS® Drug Development Process Manager Utility 2.5 Release Notes

The SAS® Drug Development (SDD) Process Manager Utility is available for SDD, version 3.5_07. New functionality has been updated in the User's Guide, however the specific areas changed are noted below.

Reference #	Title	Description
US5600	Loss of user id information over time in the	Over time, the user id column in both the
	Process Manager (PM) and Job Execution	PM and JECM was losing data. This data
	Control Editor (JECM).	loss was a result of the tail processes that
		were tailing the logs on the server losing
		contact with the log files as the logs were
		rolled. The fix for this issue was to do
		filtered logging directly into the shared
		area rather than using the tail process to
		do the filtering.
US5597	Add the managed server name to the process	A new variable was added to the process
	list in the JECM.	list in the JECM that displays the
		managed server name for each process
		and allows it to be used as a string
		variable in JECM processing.

Interim releases of the SDD Process Manager Utility are cumulative, so if this is the first time you are installing it, the release also contains the fixes shown below.

Reference #	Title	Description
PM5	Missing values for tags in the Job Execution	This issue was only a problem on systems
	Control Manager (JECM) process list on	with a multi-zone architecture and only
	multi-zone systems.	for users of the JECM. The fix for this
		issue resulted in changes to both scripts
		and code. In previous versions of the
		JECM, scripts would look in a shared area
		for SAS log files to retrieve tag values
		from the comment blocks at the top of the
		SAS code. In a multi-zone architecture,
		the shared area would only contain SAS
		logs for the processes that were originally
		run on that server. If load balancing
		caused the script to run on the other
		server, the SAS log would not be found.
		In version 2.4 of the JECM, a remote
		connection is made to the correct server
		for the process before looking in the
		shared area for the SAS log. This change
		resolved the problem of missing tags due
		to the multi-zone architecture.

Reference #	Title	Description
PM8	Add the managed server name to the process list in the Process Manager.	A new column was added to the process list in the Process Manager that now displays the managed server name for each process.
US5338	Missing user ids that resulted from concurrent writes to the log file.	The fix for this issue resulted in changes to both scripts and code. In previous versions of the Process Manager, log files from the SAS servers were aggregated into one log file, web.log, located in the shared area. In cases of a heavy load, write conflicts occurred when multiple tail processes were attempting to write to web.log. Version 2.2 of the Process Manager attempted to fix this problem by locking web.log during writes, but the lock mechanism failed on Solaris. In version 2.3, concurrent writes have been completely eliminated. There are now multiple log files in the shared area, one for each of the SAS servers. The process manager searches each of these files for process data rather than the single web.log file.
PM6	Variables CPU time and elapsed time should be integers.	The command line client, the Job Editor Control Manager (JECM), was originally documented with CPU time and elapsed time as integers so that they can be used in rules and triggers. Although they were documented as integers, they were implemented as strings. This fix converted them to integers so that all functionality of the JECM is available. For more details, see the User Reference documentation.
